

Real-time Synchronization

(Semaphores, Resources and Blocking)

Priority Inheritance

Priority Ceiling

Slack Resource Policy

The Problem

- Tasks have synchronization constraints
 - Semaphores protect critical sections
- Blocking can cause a higher-priority task to wait on a **lower-priority** one to unlock a resource
 - Problem: In all previous derivations we assumed that a task can only wait for **higher-priority** tasks not **lower-priority** tasks
- Question
 - What is the maximum amount of time a higher-priority task can wait for a lower-priority task?
 - How to account for that time in schedulability analysis?

Mutual Exclusion Constraints

- Tasks that lock/unlock the same semaphore are said to have a mutual exclusion constraint

Priority Inversion

- Locks and priorities may be at odds.
Locking results in priority inversion

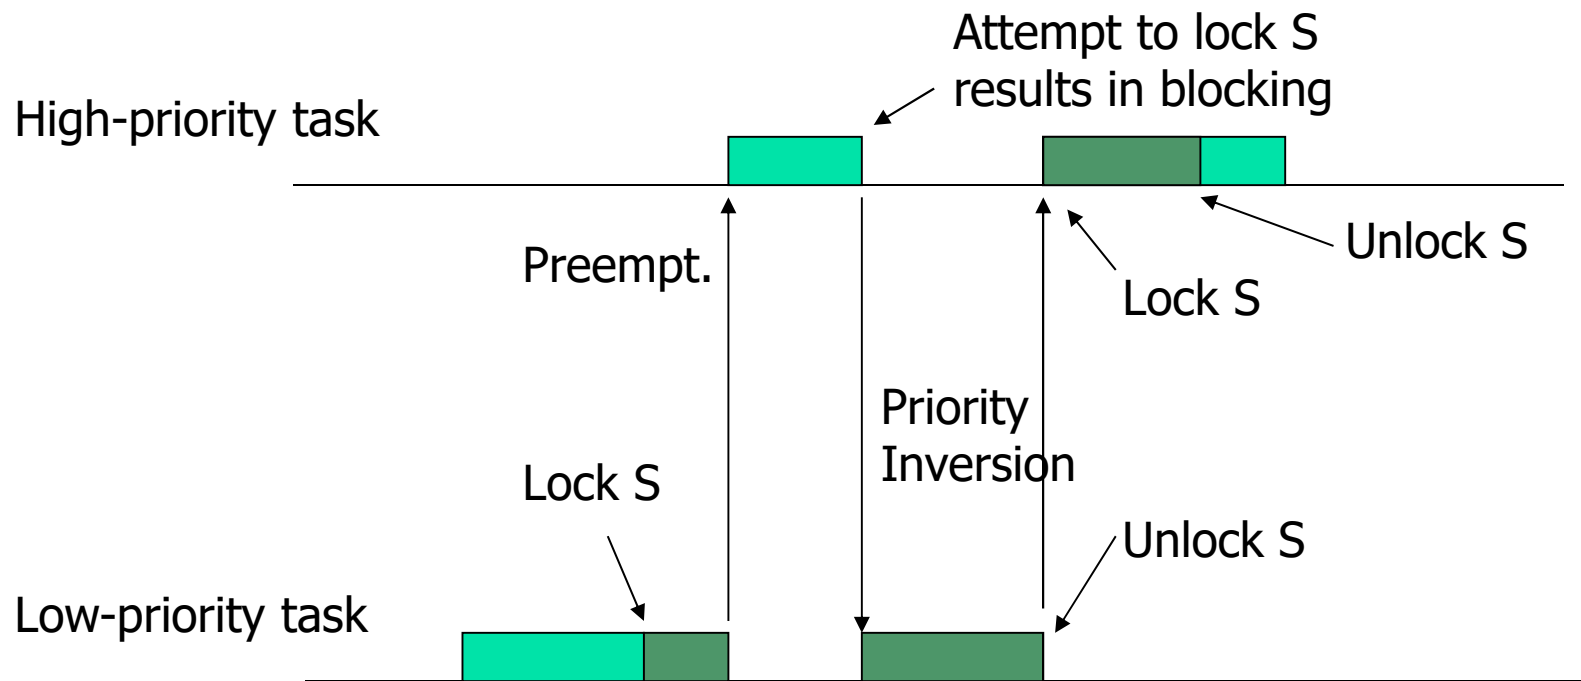

Priority Inversion

- Locks and priorities may be at odds.
Locking results in priority inversion

Priority Inversion

- How to account for priority inversion?

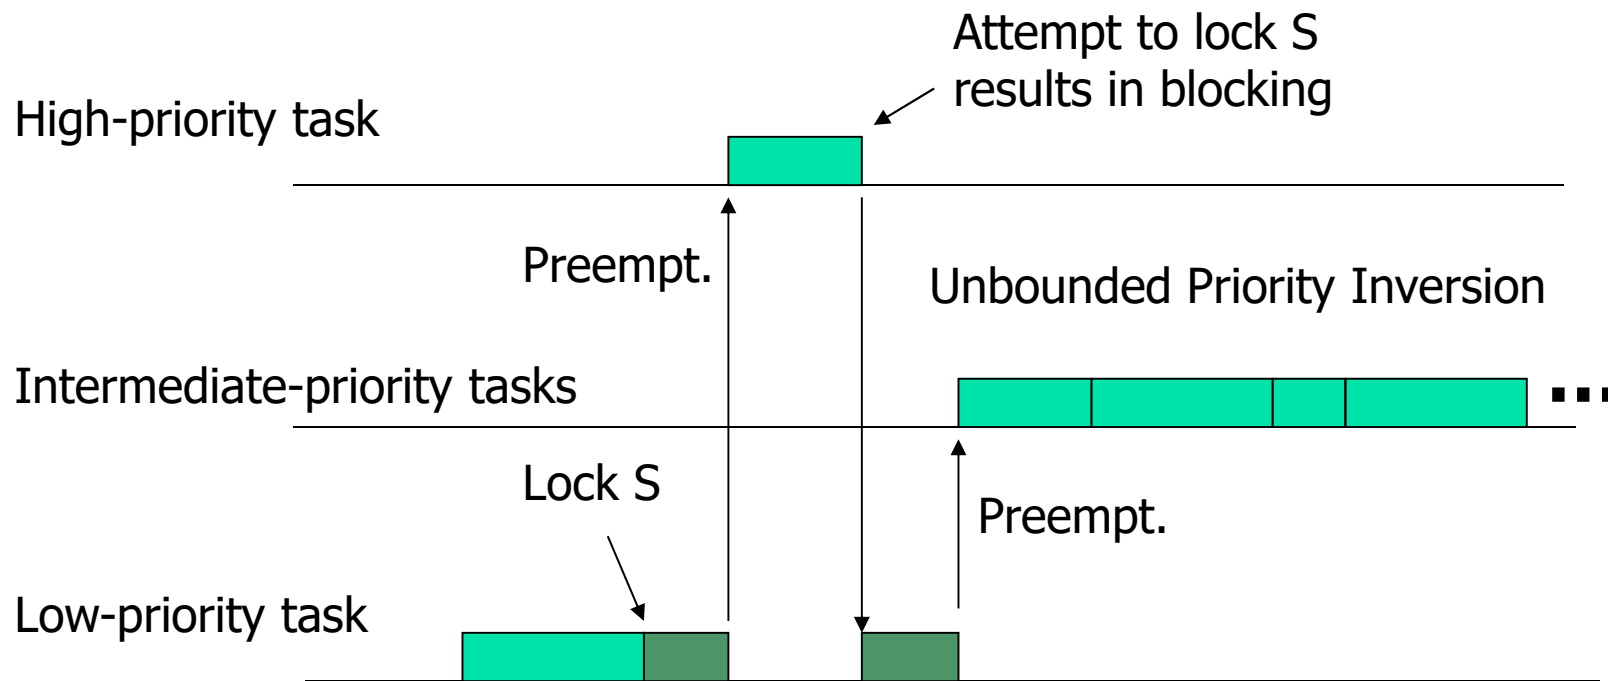

Unbounded Priority Inversion

- Consider the case below: a series of intermediate priority tasks is delaying a higher-priority one

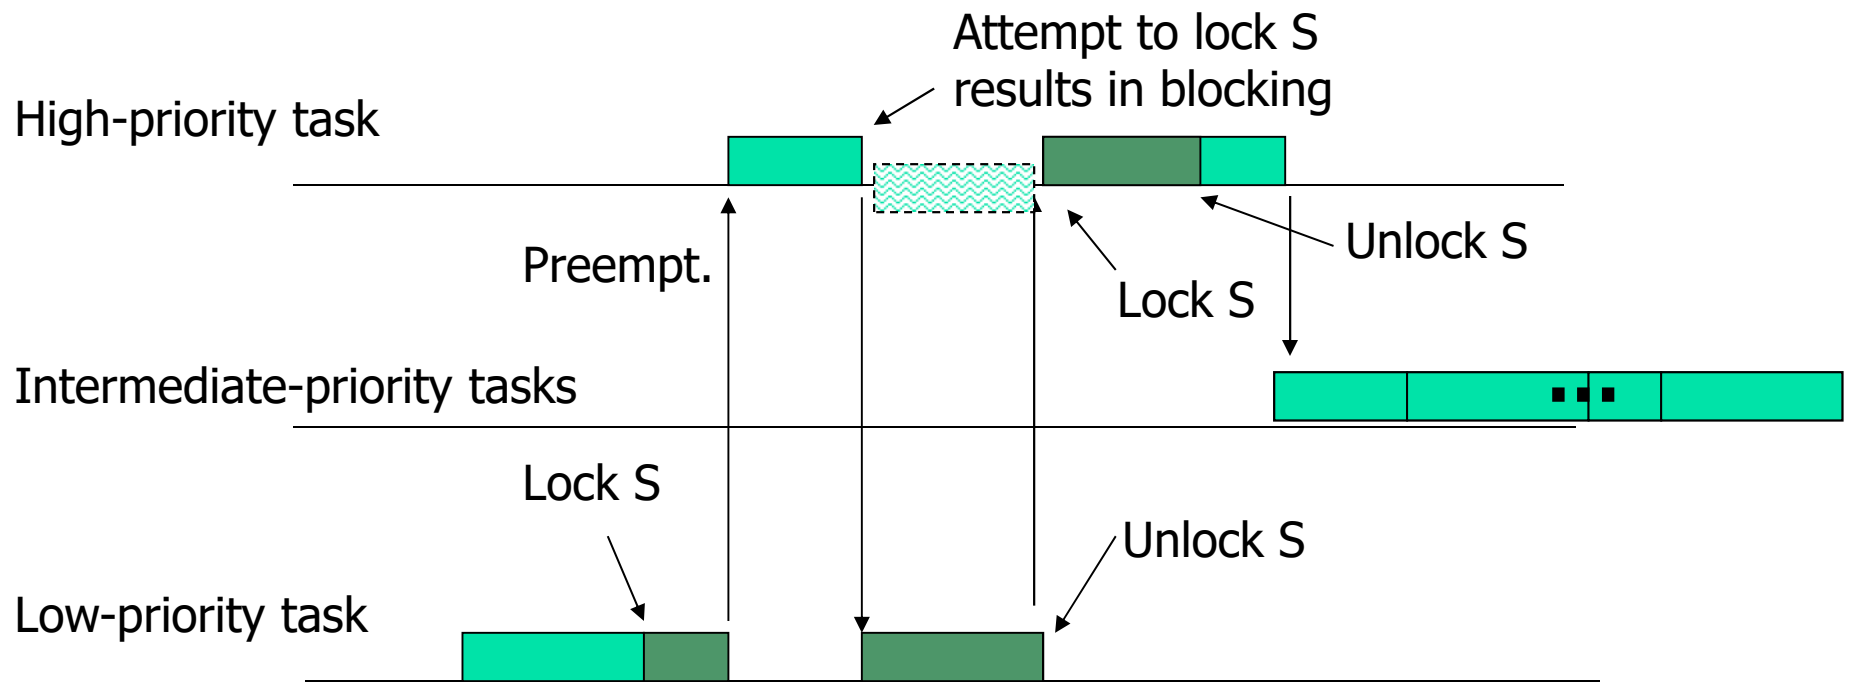

Unbounded Priority Inversion

- How to prevent unbounded priority inversion?

Priority Inheritance Protocol

- Let a task inherit the priority of any higher-priority task it is blocking

Priority Inheritance Protocol

- Question: What is the longest time a task can wait for lower-priority tasks?
 - Let there be N tasks and M semaphores
 - Let the largest critical section of task i be of length B_i
- Answer: ?

Computing the Maximum Priority Inversion Time

- Consider the instant when a high-priority task arrives.
 - What is the most it can wait for lower priority ones?

If I am a task, priority inversion occurs when

- (a) Lower priority task holds a resource I need (direct blocking)
- (b) Lower priority task inherits a higher priority than me because it holds a resource the higher-priority task needs (push-through blocking)

Maximum Blocking Time

- If all critical sections are equal (of length B):
 - Blocking time = $B \min (N, M)$
(Why?)
- If they are not equal?

Maximum Blocking Time

- If all critical sections are equal (of length B):
 - Blocking time = $B \min(N, M)$
(Why?)
- If they are not equal
 - Find the worst (maximum length) critical section for each resource
 - Add up the top $\min(N, M)$ sections in size
- The total priority inversion time for task i is called B_i

Schedulability Test

$$\forall i, 1 \leq i \leq n,$$

$$\frac{B_i}{P_i} + \sum_{k=1}^i \frac{C_k}{P_k} \leq i(2^{1/i} - 1)$$

Schedulability Test

$$\forall i, 1 \leq i \leq n,$$

$$\frac{B_i}{P_i} + \sum_{k=1}^i \frac{C_k}{P_k} \leq i(2^{1/i} - 1)$$

Why do we have to test each task separately? Why not just one utilization-based test like it used to?

Problem: Deadlock

Deadlock occurs if two tasks locked two semaphores in opposite order

Priority Ceiling Protocol

- Definition: The priority ceiling of a semaphore is the highest priority of any task that can lock it
- A task that requests a lock R_k is denied if its priority is not higher than the highest priority ceiling of all currently locked semaphores (say it belongs to semaphore R_h)
 - The task is said to be blocked by the task holding lock R_h
- A task inherits the priority of the top higher-priority task it is blocking

Problem: Deadlock?

Deadlock used to occur if two tasks locked two semaphores in opposite order. Can it still occur in priority ceiling?

Problem: Deadlock?

Deadlock used to occur if two tasks locked two semaphores in opposite order. Can it still occur in priority ceiling?

Lock R2: **Denied because its priority is not higher than ceiling of R1**

Priority Inheritance Protocol

Schedulability

- A task can be preempted by only one critical section of a lower priority task (that is guarded by a semaphore of equal or higher priority ceiling). Let max length of such section be B_i

$$\forall i, 1 \leq i \leq n,$$

$$\frac{B_i}{P_i} + \sum_{k=1}^i \frac{C_k}{P_k} \leq i(2^{1/i} - 1)$$
